## [ III ] Store

### Explanation

#### Store Server Tasks

- RFID Antennas INPUT
  1. Keeps track of new inventory coming in
  2. Keeps track of products that go in the Shop Floor
  3. Keeps track of in-store storage
  4. Keeps track of products leaving the store
- Keep track of inventory and suggest to managers which products have a near BB date
- Calculate the transport time.
- Automatic counting
  - $\text{products} = \text{productsIn} - \text{productsOut}$
  - $\text{productsInShopFloor} = \text{products} - \text{productsInStorage}$
- Show managers the list of products that need to be reduced on that day
  - employees won't have to check all the products
  - they will have to check only the products that have the BB date that needs to be reduced
  - (If there is an RFID checkout, the reduction can be done automatically)
- There might be an RFID self-checkout system, where the customers won't have to scan the bar code, but just put their basket near an RFID antenna, and the system will scan all the items automatically.
- If there is an RFID checkout, the system can identify items/products that leave the shop unpaid
- There might be a portable RFID reader that scans all the products on the shelves.
- And many more...
